

# CorText Platform is for You

BARBIER Marc  
UMR LISIS, INRA  
Director of CorText Platform

# The big picture of challenges

## An Epistemic Challenge for STS Researchers

- Pixelisation of sciences/society debates on the web
- Streams of d@t@ in any production system or business activities
- Time and Space of Research Activities (extraction of massive set of data, artificial experimenting, practices accountability)

## Political Changes with Science-in-Society Accountability

Tools & Skills for Science Policy following an Alliance of Artificial Intelligence and Human & Social Sciences: library sciences, scientometrics, research management, collaborative accountability, web design

## A technological Challenge for old-IA

Tools & Skills for the design of technological platforms for research: pluridisciplinary work between IT Engineers, Linguistic and Information Science and Human & Social Scientists (historian, sociologist, economist,...)

# Goal and aims

## GOAL

To provide a **digital platform available** to « RISIS research groups » and to impact the practices of Research in Science policy and Science-Technology-Studies

## AIMS

- to equip scientists with tools that enable them to tackle the complexity of heterogeneous textual corpora dynamics
- to develop innovative analytical methodologies that will bring new insights and renewed capacities to investigate contemporary issues of Sciences Innovation and Technology in Society

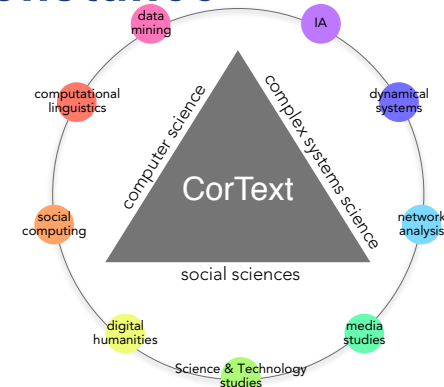

## The CorTexT.Risis team provides

- Tools, process, scripts, procedures and methods encapsulated in an On-Line Open Access Digital Platform: [www.cortext.risis.eu](http://www.cortext.risis.eu)
- Skills, methods and training competencies to be mobilized in Training Session and projects of RISIS Associated Labs

# CorText Team

# "Big-data": also a challenge for Humanities

nature

Vol 455/4 September 2008

## COMMENTARY

### How do your data grow?

Scientists need to ensure that their results will be managed for the long haul. Maintaining data takes big organization, says **Clifford Lynch**.

Data can be 'big' in different ways. National and international projects such as the Large Hadron Collider (LHC) at CERN, Europe's particle-physics laboratory near Geneva in Switzerland, or the Large Synoptic Survey Telescope for northern Chile, are frequent examples of how they will challenge the science of computation, networking and storage. But research data can also be big because of its lasting significance — a clinical observation of a unique event, or a big because of descriptive context such as the experimental conditions. Because digital data are so easily replicated and so recombinable, they present tremendous reuse opportunities for investigations already under way, and the advantage of past investments.

To enable reuse, data must be managed. In some cases the effects of data loss are economic, because experiments are lost. In other cases, data loss represents a loss of knowledge that is lost forever. Funders now see data as assets that they are underwriting, and the greatest pay-off for their investment is the demand that researchers and host institutions document and implement data-management and data-sharing plans that address the full life cycle of data — including what happens after a grant finishes. Host universities thus find themselves with legal and ethical obligations to provide a legacy of faculty data. Publishers must also identify the most effective ways to connect publications with data and preserve the scientific record.

#### Developing infrastructure

Managing the life cycle of scientific data presents many challenges. These include deciding responsibilities, funding, resource allocation, what data should be kept and for how long.

In a sense, landmark international projects like the LHC are the least problematic: the costs of data management are explicit in the budget and tend to be dominated by technology issues that decline over time. These projects also include dedicated personnel; and, although the volume of data is often vast, the streams fit within well defined descriptive schemes.

But science's reliance on digital data extends

example, have invested substantially in common infrastructure for a more systematic reliance on data, networks and computation. And there are vast numbers of scientific research projects producing at most a few terabytes per year of big data, or data that can be aggregated into a big-

information management tasks to a rotating staff of students and postdocs. Indeed, as specific data sets become distant from current research activities, stewardship can become a tax on scientific productivity.

Scientists need to act responsibly during their working lives, by developing standards and recording experiments in a way that allows for data when the data are no longer needed. Experimental metadata, experimental results, and experimental procedures, for example, can be recorded in a way that allows for data when the data are no longer needed. Experimental metadata, experimental results, and experimental procedures, for example, can be recorded in a way that allows for data when the data are no longer needed.

Ultimately, the best stewardship of data will come from disciplinary engagement with preservation institutions. General-purpose data management as provided by universities through their research libraries will have its limits. Where there is no natural locus of disciplinary stewardship, universities will need to establish consortia to enable disciplines to create and sustain such engagement.

possible here. In 2007, the US National Science Foundation, recognizing the importance of such standards, established the Community Based Data Interoperability Networks (INTEROP) funding programme for the development of tools, standards and data management best practices within specific disciplinary communities. INTEROP should make its first awards this autumn. Although many classes of scientific data aren't ready, or aren't appropriate, for standardization, well chosen investments in standardization show a consistently high pay-off.

At the start of the data life cycle, individual scientists will have primary responsibility for stewardship. But longer term, data preservation can only be done by institutions. If data are to be consolidated or shared on a frequent basis, there is a lot to be said for moving to institutional control sooner rather than later. Scientists are not necessarily good data managers and can more fruitfully spend their time doing science.

"The best stewardship of data will come from engagement with preservation institutions."

short term, it is use. In a high-throughput university's network, machines will often be compromised if updates aren't applied; this can mean data destruction or corruption. Disasters such as Hurricane Katrina, which destroyed labs and computing facilities, are important reminders that data need to be backed up

frequently and comprehensively in diverse and distant locations. Appropriate use of IT services such as secure storage or hosting from the host institution may be valuable. In the longer term, digital data is at risk from various forms of technological obsolescence (particularly if locally held removable storage media are used). There is a need for new institutional services that can help with all these needs, handling traditional IT issues and information-management issues more familiar to librarians and archivists.

At some point, the primary copy needs to migrate to an institutional service. Today, these services are sparse. In the United Kingdom there are data services associated with several

#### ABSTRACT

For several decades taxonomy has been marginalized in academic labs and universities. Today, rising concerns over biodiversity and ecosystem services are creating an unprecedented opportunity for it to be viewed as a crucially relevant field. This article aims to scrutinize how the biodiversity concerns entail new collaboration designs between taxonomists and nature managers and between taxonomists and ecologists. Our key point is that taxonomy's environmental relevance is not given: instead, taxonomic data have to be made relevant by taxonomists and their partners in specific collaborative and organizational arrangements. The article draws on an empirical study of an All Taxa Biodiversity Inventory (ATBI) in a national park in the French Alps, including an ethnographic survey combined with scientometric analysis. It was found that the collaboration initiated in the ATBI between taxonomists, ecologists and the park managers was paved with disappointments and reorientations because it partly failed to address the tension between a taxonomic and an ecological approach to the relevance of taxonomic data. The rise of biodiversity and ecosystem services concerns constitutes a “double-edged sword” for taxonomists: while there is greater opportunity for taxonomists to render their work visible through new research collaboration arrangements with ecologists, it also entails a risk that they remain mere data providers for nature managers and ecologists interested in ecosystem functioning.

## Chapter 4

### Textual analysis and scientometric mapping of the dynamic knowledge in and around the IFSA community

Marc Barbier, Marianne Bompert, Véronique Garandel-Batifol,  
and Andréi Mogoutov

**Abstract** *Using the proceedings of six European IFSA Symposia, we analysed the themes that were central in these Symposia as well as trends from a number of papers and authors. We then assessed the wider domain of agricultural research based on a corpus extracted from the CAB and SCI databases of the Web of Knowledge. The co-word analysis allows the generation of maps which graphically represent how keywords are linked, and allows the identification of thematic clusters. The dynamic of keywords in the period 1991–2007 was also analysed, thus allowing the identification of keywords which were of central importance during different periods. This showed how themes such as sustainability emerged, disappeared and re-emerged under different guises. The various analyses are provided to further the reflexivity of the IFSA community, especially regarding its publication practices and thus its efforts to make results from Farming Systems Research more widely available.*

#### ABSTRACT

We performed a quantitative and qualitative analysis of the scientific literature on ecosystem services in order to help tracing a research agenda for agricultural sciences. The ecosystem services concept now lies at the heart of current developments to address global environmental change. Do agricultural sciences generate knowledge that covers this emerging theme? An analysis of scientific production allowed us to return to the ecological origins of this concept and see how little it has been appropriated by agricultural sciences until now, despite major focus on the issue of agro-ecosystems in the literature. Agricultural sciences tend to be more active in the field of environmental services, defined as services rendered by humans to ecosystems. The main studied services are those which have already been clearly identified and which act in synergy. Less attention is paid to the antagonisms between different services. These findings call for the implementation of agricultural research programmes that will consider the socio-agro-ecosystem as a whole and broaden the traditional issues addressed by agricultural sciences. We insist on three main management and operational issues that needs to be overcome if this is to be done: working at the landscape scale, increasing inter-disciplinary collaborations and take uncertainties into account.
